## 25 ABSTRACT

26

27 The level of humoral immunoreactivity to total cows' milk proteins (TCMP) in sera of patients  
28 suffering from recurrent oral ulcerations, gastrointestinal diseases or haematological  
29 malignancies was investigated. TCMP were also hydrolysed with two different species of  
30 lactobacilli and dramatic changes in the levels of specific IgG and IgE were found with  
31 statistically significant decreases in the levels of specific antibodies in sera from all patient  
32 groups. The levels below cut-off values of IgG specific for TCMP hydrolysates were detected in  
33 sera from all patients, while values of IgE for hydrolysates obtained with *Lactobacillus*  
34 *helveticus* BGRA43 and *Lactobacillus zae* LMG17315 were below cut-off in 85% and 97% of  
35 patients, respectively. Competitive ELISA confirmed the specificity of antibodies for  
36 immunogenic TCMP epitopes, demonstrating that lactobacilli hydrolyse TCMP by degrading  
37 immunogenic epitopes, and could therefore be used in processing of milk proteins to obtain  
38 products suitable for patients with altered immune response on TCMP.

39

## 40 1. Introduction

41

42 Lactobacilli are a major and diverse group of lactic acid bacteria, irreplaceable in the  
43 production of an array of fermented milk products that have been manufactured for centuries  
44 worldwide. Numerous studies have been conducted to understand the processes underlying  
45 bacterial fermentation of milk and to ascertain the ways and mechanisms by which lactobacilli  
46 can contribute to human health. It has been determined that these bacteria can promote human  
47 health through various mechanisms, such as modulation of immune system, affecting pathogen  
48 exclusion, or influencing different microbial/host products (Oelschlaeger, 2010).

49 One of the most important features of lactobacilli used in dairy industry is their  
50 proteolytic system, responsible for digestion and utilisation of milk proteins. Bacterial  
51 proteolysis of milk proteins may lead to generation of various bioactive peptides with  
52 immunomodulatory, antihypertensive, antioxidative, antimicrobial and other health-promoting  
53 properties (Hayes, Stanton, Fitzgerald, & Ross, 2007; Wakai & Yamamoto, 2012). In addition, it  
54 was recently discovered that proteinases of some probiotic lactobacilli have anti-inflammatory  
55 activity (Hörmannsperger, von Schillde, & Haller, 2013; von Schillde et al., 2012). Positive  
56 clinical effects of lactobacilli supplementation were shown in patients with allergic and  
57 inflammatory skin disorders (Hacini-Rachinel et al., 2009), different gastrointestinal disorders  
58 (Verna & Lucak, 2010), chronic inflammation-associated sickness behaviour (D'Mello et al.,  
59 2015), and other inflammation-related diseases. These findings put lactobacilli in the centre of  
60 future development of therapies for numerous inflammation-related diseases.

61 One of the immune-related diseases that significantly affects the quality of life of people  
62 from both developed and developing countries is food allergies, with prevalence of 5% in adults

63 and 8% in preschool children (Sicherer & Sampson, 2014). Considering that milk is one of the  
64 most exploited and consumed food products throughout the world, frequency and severity of  
65 milk allergies are medical issues of great importance (Schreier & Wright, 2014; Warren, Jhaveri,  
66 Warriar, Smith, & Gupta, 2013). While various milk processing technologies have been  
67 examined for reducing the allergenicity of different cows' milk proteins (CMP) (Ehn, Ekstrand,  
68 Bengtsson, & Ahlstedt, 2004; Peyron, Mouécoucou, Frémont, Sanchez, & Gontard, 2006),  
69 several studies have demonstrated favourable effects of milk fermentation by different strains of  
70 lactic acid bacteria (Bu, Luo, Zhang, & Chen, 2010; El-Ghaish et al., 2011; Kleber, Weyrich, &  
71 Hinrichs, 2006; Pescuma et al., 2015; Shi et al., 2014).

72         Alongside patients with diagnosed milk allergies, it has been shown that patients  
73 suffering from gastrointestinal disorders can possess excessive immunoreactivity towards cows'  
74 milk proteins, as well as to other food proteins, like gliadin, a main component of gluten (Besu et  
75 al., 2009). Similar results were obtained for patients with multiple myelomas and non-Hodgkin  
76 lymphomas (Juranic et al., 2008, 2009). Moreover, this reactivity can play a role in the aetiology  
77 of recurrent aphthous ulcerations, one of the most common but poorly understood oral diseases.  
78 The cows' milk free diet in these patients resulted in decrease in the levels of antibodies specific  
79 for CMP and remission of clinical symptoms (Besu et al., 2009, 2013). In addition, CMP-free  
80 diet in one patient with monoclonal gammopathy (immunological disorder that could be the  
81 precursor of multiple myeloma, or lymphoma) led to disappearance of the "M" component  
82 (monoclonal IgG ( $\lambda$ ) immunoglobulins). This was associated with the drop-off in the levels of  
83 anti-CMP IgG (from 892 AU mL<sup>-1</sup> to 0 AU mL<sup>-1</sup>) and anti-CMP IgA antibodies (from 240 AU  
84 mL<sup>-1</sup> to 0 AU mL<sup>-1</sup>), as reported by Juranic et al. (2009). These results indicate the potential

85 benefit of using non-immunogenic products consisting of hydrolysed CMP in nutrition of these  
86 patients.

87         Since there is no consensus about the impact of an individual milk protein or a particular  
88 structure to development of humoral immune response against CMP (Gaudin et al., 2008;  
89 Pelaez-Lorenzo, Diez-Masa, Vasallo, & de Frutos, 2010; Wal, 2004), it is prudent to consider  
90 that all milk proteins may contribute to immune response. Considering that our previous results  
91 pointed to possible association of humoral immune response against CMP with different non-  
92 allergic, immune-related diseases, the aim of this study was to investigate whether lactobacilli  
93 hydrolysis of total cows' milk proteins (TCMP) can abrogate elevated humoral immunity to  
94 TCMP in these patients. For this purpose, sera from patients suffering from recurrent oral  
95 ulcerations, different gastrointestinal disorders and haematological malignancies were tested for  
96 changes in TCMP-immunoreactivity after treatment of cows' milk with preselected strains of  
97 lactobacilli. Considering that substrate specificity of proteinases differs greatly among  
98 lactobacilli species, ten different potential probiotic strains were selected for analysis of their  
99 proteolytic activity. Two strains that showed the best proteolytic potential, *Lactobacillus*  
100 *helveticus* BGRA43 and *Lactobacillus zaeae* LMG17315, were further used for TCMP hydrolysis.

101

## 102 **2. Methods**

103

### 104 *2.1. Patients*

105

106         Sera were collected from three groups of patients (20 in each group) as well as from  
107 healthy volunteers. The first group of 20 patients had recurrent oral ulcerations (ROU), the

108 second group of 20 patients had different gastrointestinal disorders [GD; 12 patients with coeliac  
109 disease, 4 patients with ulcerative colitis, 2 patients with inflammatory bowel disease (IBD) and  
110 2 patients with Chron's disease], and the third group of 20 patients had different haematological  
111 malignancies (HM) before oncological therapy [11 patients with non-Hodgkin lymphoma  
112 (NHL), 4 patients with multiple myeloma and 5 patients with plasmacytoma]. The control group  
113 for determining reference cut-off values for bacterial antigens consisted of 33 healthy control  
114 subjects.

115 To confirm elevated humoral immunity against TCMP, the levels of IgG and IgE  
116 antibodies specific for TCMP were tested in sera of patients from all groups, as both isotypes of  
117 antibodies have been shown to play function in anaphylactic reaction (Johnston, Chien, & Bryce,  
118 2014). The reference cut-off values for anti-TCMP IgG (39 AU mL<sup>-1</sup>) and anti-TCMP IgE  
119 antibodies (10 AU mL<sup>-1</sup>) were determined by analysing sera samples of 50 healthy control  
120 subjects (Besu et al., 2009; Juranic et al., 2009). Analyses of humoral immunity to cows' milk  
121 proteins in patients' sera were approved by the Ethics Committee of the Institute of Oncology  
122 and Radiology of Serbia and Ethics Committee of the Clinical Centre of Serbia. Written  
123 informed consent was obtained from each patient.

124

## 125 2.2. *Bacterial strains, media and culture conditions*

126

127 Six different lactobacilli strains (*Lb. helveticus* BGRA43, *Lactobacillus rhamnosus*  
128 BGT10, *Lactobacillus plantarum* BGPV2-45a, *Lb. plantarum* BGBUK2-5, *Lb. plantarum*  
129 BGG8-8, *Lb. plantarum* BGHO10) from our laboratory collection (Laboratory for Molecular  
130 Microbiology, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade),

131 as well as four different lactobacilli strains from international collections (*Lactobacillus casei*  
132 ATCC393 from American Type Culture Collection and *Lb. zae* LMG17315, *Lb. plantarum*  
133 LMG9208 and *Lb. plantarum* LMG18024 from Belgian Co-ordinated Collections of Micro-  
134 organisms) were screened for proteolytic activity against TCMP. Bacterial cells were generally  
135 grown and maintained in MRS broth (Merck, GmbH, Darmstadt, Germany) at 30 °C. *Lb.*  
136 *helveticus* BGRA43 was grown and maintained under anaerobic conditions in anaerobic jars  
137 using Anaerocult A (Merck) at 37 °C. Stocks of cultures were kept at -80 °C in MRS broth  
138 containing 15% (v/v) glycerol. Agar plates were prepared by adding 1.5% (w/v) agar (Torlak,  
139 Belgrade, Serbia) to MRS broth. For the test of proteolytic activity, cells were grown at  
140 appropriate temperature on milk-citrate agar (MCA) plates with 4.4% reconstituted non-fat skim  
141 milk, 0.5% glucose, 0.8% trisodium citrate, 0.1% yeast extract and 1.5% agar (w/v).

142

### 143 2.3. *Proteinase activity assay*

144

145 Proteolytic activity of the *Lactobacillus* strains was assayed as described previously  
146 (Kojic, Fira, Banina, & Topisirovic, 1991), with the following modification: as a substrate in  
147 reactions, milk powder (Mlekara Subotica AD, Subotica, Serbia) was used. Milk powder was  
148 dissolved in 100 mM sodium phosphate buffer at concentration of 20 mg mL<sup>-1</sup> (w/v), which  
149 resulted in a final protein concentration of 5 mg mL<sup>-1</sup>. The cell suspension dissolved in the same  
150 buffer and containing 10<sup>9</sup> cells mL<sup>-1</sup> was mixed with milk powder solution at a 1:1 (v/v) ratio and  
151 incubated for 3 h at 37 °C. Controls for bacterial antigens (RA and Z antigen solutions) were  
152 obtained by incubating cell suspensions for 3 h at 37 °C, pelleting the cells and collecting the

153 supernatants. Quantification of protein bands on sodium dodecyl sulphate-polyacrylamide gel  
154 electrophoresis (SDS-PAGE) was done using ImageJ.

155

156 2.4. *Determination of the levels of IgG and IgE specific for undigested TCMP and for two*  
157 *TCMP hydrolysates in patients' sera by enzyme-linked immunosorbent assay*

158

159 Determinations of the levels of IgG and IgE specific for undigested TCMP and two  
160 TCMP hydrolysates (TCMP-RA and TCMP-Z obtained after digestion with *Lb. helveticus*  
161 BGRA43 and *Lb. zaeae* LMG17315, respectively) were done by enzyme-linked immunosorbent  
162 assay (ELISA) tests, as described previously (Besu et al., 2009; Juranic et al., 2009). In addition,  
163 levels of antibodies to bacterial antigens possibly present in the working solutions (RA and Z  
164 antigen solutions) were also determined.

165 Briefly, 100  $\mu\text{L}$  of antigen solutions (TCMP, TCMP-RA hydrolysate, TCMP-Z  
166 hydrolysate, RA and Z antigen solutions) in bicarbonate buffer, pH 9.5, were added to  
167 polystyrene 96-well microtitre ELISA plates at a concentration of  $10 \mu\text{g mL}^{-1}$  (F96 MaxiSorp  
168 Nunc-Immuno Plate, Waltham, MA, USA). Wells were incubated at  $4^\circ\text{C}$  for 24 h enabling  
169 antigens to bind to polystyrene surface. The next day coated wells were washed and free sites on  
170 the polystyrene surface were blocked with 1% bovine serum albumin (BSA; Sigma Aldrich, St  
171 Louis, MO, USA) by incubating for 60 min at room temperature. After washing and aspiration,  
172 50  $\mu\text{L}$  of sera samples (dilution 1/100) were added into appropriate wells and incubated for 60  
173 min at room temperature with subsequent aspiration and washing. Horseradish peroxidase-  
174 labelled secondary antibodies were used for detection of primary antibodies bound to antigen  
175 [sheep anti-human IgG (binding site) and goat anti-human IgE (Sigma Aldrich)]. Appropriate

176 wells were filled with 50  $\mu$ L of secondary antibody solution and plates were incubated for 60  
177 min at room temperature and then washed five times. One hundred microlitres of substrate  
178 solution 3,3',5,5'-tetramethylbenzidine (TMB; INEP, Zemun, Serbia) was added to the wells and  
179 after short incubation (5–10 min), the enzyme reaction was terminated by addition of sulphuric  
180 acid (50  $\mu$ L). The optical density (OD) of the developed colour was measured at 450 nm using a  
181 microplate reader (Multiskan EX; Thermo Scientific, Waltham, MA, USA).

182 The absorbance of the appropriate blank was always subtracted from the absorbance of  
183 the corresponding sample. The levels of serum IgG and IgE antibodies were presented in  
184 arbitrary units (AU)  $\text{mL}^{-1}$ . Human sera with the highest anti-TCMP IgG and IgE levels were used  
185 for the calibration.

186 Intra-assay coefficient of variation was not higher than 4%, while inter-assay coefficient  
187 of variation was not higher than 3%.

188 For determination of the immunoreactivity related only to cows' milk epitopes, the level  
189 of antibodies in each serum sample incubated with RA or Z antigen solutions was always  
190 subtracted from the level of antibodies in the corresponding serum sample incubated with  
191 TCMP-RA or TCMP-Z hydrolysates. Reference cut-off values for RA and Z antigens were  
192 determined by analysing the sera of 33 healthy control subjects.

193

#### 194 2.5. *Examination of antibody specificity by competitive ELISA*

195

196 Competitive ELISA was performed to confirm the specificity of detected anti-TCMP  
197 antibodies. The sera of five patients with ROU or GD (coeliac disease patients) who had the

198 highest levels of antibodies specific for antigenic determinants of unhydrolysed TCMP were  
199 chosen for these analyses. For each competitive ELISA test the pool of five sera was made.

200 To each well of 96-well microtitre ELISA plate 100  $\mu\text{L}$  of unhydrolysed TCMP solution  
201 ( $10 \mu\text{g mL}^{-1}$ ; dissolved in bicarbonate buffer, pH 9.5) was added. Wells were incubated at  $4^\circ\text{C}$   
202 for 24 h. After washing and blocking of wells with BSA, 50  $\mu\text{L}$  of each examined solution ( $100^{-1}$   
203 dilution of 5 pooled sera with added solutions of TCMP, or TCMP-RA hydrolysate or TCMP-Z  
204 hydrolysate (final concentrations: 0, 1, 10, 100, 500 and  $1000 \mu\text{g mL}^{-1}$ , made in 1% BSA/TTBS)  
205 were added to appropriate wells. After 60 min incubation at  $37^\circ\text{C}$ , the primary antibodies bound  
206 to TCMP immobilised on the polystyrene surface of the well were detected using HRP-labelled  
207 secondary antibodies and TMB, as described previously.

208

## 209 2.6. *Statistical analysis*

210

211 Friedman Test with Dunn's Post Test was used for statistical analysis of differences  
212 between the levels of IgG or IgE against TCMP, TCMP-RA and TCMP-Z in patients' sera. Only  
213 the patients with the levels of anti-TCMP antibodies above cut-off values were statistically  
214 analysed. Statistical package GraphPad Prism 5 was used for statistical analysis and preparation  
215 of graphs.

216

## 217 3. **Results**

218

### 219 3.1. *Hydrolysis of milk proteins*

220

221 The proteolytic potential of ten selected lactobacilli strains was assessed following the  
222 hydrolysis of TCMP (Fig. 1). Strains *Lb. zeae* LMG17315 (lane 3) and *Lb. helveticus* BGRA43  
223 (lane 10) demonstrated the best proteolytic activity, judging from SDS-PAGE patterns of TCMP  
224 degradation, and these two strains were used for further investigation. As can be seen from the  
225 gel, all casein fractions were completely hydrolysed with both LMG17315 and BGRA43. In  
226 addition, BGRA43 almost completely (over 80%) hydrolysed whey proteins, while their  
227 hydrolysis with LMG17315 was partial, as bands of  $\beta$ -lactoglobulin and  $\alpha$ -lactalbumin were still  
228 detectable after the reaction. ImageJ quantification indicated that LMG17315 hydrolysed about  
229 70% of  $\alpha$ -lactalbumin and 60% of  $\beta$ -lactoglobulin (data not shown). It should be noted that three  
230 distinct bands of higher molecular masses visible in lane 10 are bacterial proteins, most probably  
231 cell surface proteins, originating from BGRA43 (Banina et al., 1998; Fira et al., 2001).

232

### 233 3.2. Immunoreactivity to TCMP and TCMP hydrolysates

234

235 Fifty-two of 60 patients (87%) analysed in this study had elevated serum levels of IgG  
236 and/or IgE antibodies to TCMP. Each patient with elevated level of IgG specific for TCMP (16  
237 ROU patients, 9 HM patients and 11 GD patients) also had elevated level of anti-TCMP IgE. In  
238 addition, 3 ROU patients, 6 HM patients and 7 GD patients had elevated levels of IgE specific  
239 for TCMP, while the levels of anti-TCMP IgG were below the cut-off value in their sera.

240 When considering the patients with above cut-off levels of anti-TCMP IgG and/or IgE,  
241 all of them had lower IgG and IgE levels specific for both examined hydrolysates (Fig. 2). The  
242 levels of IgG specific for TCMP hydrolysates were below the cut-off value in sera of all patients  
243 (Fig. 2A, C, E). Similarly, the levels of IgE specific for TCMP hydrolysates were significantly

244 lower in all patients, compared with the levels of anti-TCMP antibodies (Fig. 2B, D, F). Values  
245 below the cut-off of IgE specific for RA-hydrolysates were detected in 85% of patients, while  
246 97% of patients had the same for Z-hydrolysates.

247

### 248 3.3. *Immunoreactivity to bacterial antigens*

249

250 In parallel, we examined the patients' sera for the levels of IgG and IgE specific for the  
251 bacterial cell surface proteins or other antigens possibly present in the working solutions (RA  
252 and Z antigen solutions). As expected, the results indicated the presence of antibodies against  
253 bacterial antigens in the examined groups of patients, as well as in healthy control subjects.  
254 Frequencies of healthy control subjects and patients with elevated levels of antibodies to RA and  
255 Z antigen solutions are displayed in Table 1. All patients groups showed higher reactivity to Z  
256 antigen solution.

257 To confirm that levels of IgG and IgE detected in experiments with TCMP hydrolysates  
258 are specific for immunogenic epitopes in unhydrolysed TCMP, we performed the competitive  
259 ELISA tests using pool of five sera of ROU patients (Fig. 3) and pool of five sera of patients  
260 with coeliac disease (data not shown). The sera used in competitive ELISA tests were from the  
261 patients who showed the highest immunoreactivity to TCMP. The levels of detected anti-TCMP  
262 IgG and IgE antibodies were decreasing proportionally as the concentration of free undigested  
263 TCMP was increasing, while this effect was not observed with addition of free TCMP-RA or  
264 free TCMP-Z hydrolysates (Fig. 3).

265

#### 266 4. Discussion

267

268 Numerous studies focused on peptides released during fermentation of milk by  
269 *Lactobacillus helveticus* strains, and revealed their antihypertensive, immunomodulatory and  
270 even antitumor properties (LeBlanc, Matar, Valdéz, LeBlanc, & Perdigon, 2002; Vinderola,  
271 Matar, & Perdigón, 2007; Wakai & Yamamoto, 2012). The antimicrobial, technological and  
272 probiotic potential of *Lb. helveticus* BGRA43, as well as its proteolytic system, has been  
273 previously characterised in detail by our group (Strahinic et al., 2013a,b). BGRA43 possesses  
274 large extracellular proteinase PrtH, which is capable of hydrolysis of all casein fractions, as well  
275 as degradation of one of three major allergenic epitopes of  $\beta$ -lactoglobulin (Lozo et al., 2011;  
276 Strahinic et al., 2013b). It has been established that fermentation of milk by BGRA43 releases  
277 peptides that express significant anti-inflammatory properties on the Nd-THP-1 monocyte cell  
278 line due to down-regulation of tumour necrosis factor- $\alpha$  or interleukin-6 production (Tompa et  
279 al., 2011). On the other hand, the proteolytic system of *Lb. zaeae* LMG17315 is only partially  
280 characterised, but it is known that this strain possesses proteinases that differ greatly from the  
281 one present in BGRA43 (Kim et al., 2011; Vukotić et al., 2016).

282 In this study we investigated the ability of proteinases of these two lactobacilli to  
283 hydrolyse TCMP for which elevated levels of specific IgE and IgG were previously determined  
284 in ROU, HM and GD patients (Besu et al., 2009, 2013; Juranic et al., 2008, 2009). We showed  
285 that the levels of antibodies specific for TCMP hydrolysates obtained in this way were below  
286 cut-off values for the majority of tested patients indicating that the most of IgG and IgE specific  
287 epitopes were destroyed by bacterial hydrolysis.

288           The most remarkable difference was observed with the levels of IgG, given that no  
289 patient expressed above cut-off levels of the antibodies either against TCMP-RA or TCMP-Z  
290 hydrolysate. The role of IgG immunoglobulins in cows' milk hypersensitivity is quite  
291 controversial. Anthoni, Savilahti, Rautelin, and Kolho (2009) reported the existence of  
292 association between levels of milk proteins specific IgG antibodies and gastrointestinal  
293 symptoms in adults. The IgG4 immunoglobulins seems to have an immunopathological role in  
294 the non-IgE-mediated cows' milk allergy with delayed gastrointestinal symptoms (Sletten,  
295 Halvorsen, Egaas, & Halstensen, 2006). In addition, even though the IgE pathway of anaphylaxis  
296 has been well characterised, the existence of an IgG pathway is controversial in humans  
297 (Khodoun, Strait, Armstrong, Yanase, & Finkelman, 2011). However, the cases of anaphylaxis  
298 developed after repeated infusion of large amounts of dextran (Hedin et al., 1980), von  
299 Willebrand's factor (Bergamaschini et al., 1995), or therapeutic IgG mAbs (Klasterky, 2006)  
300 that have been characterised by the presence of detectable IgG, but not IgE Abs, to the infused  
301 compound may be the most likely candidates for human IgG-mediated anaphylaxis.

302           Considering the importance of IgG highlighted in these publications, achievement of a  
303 below cut-off decrease of IgG to TCMP in all patients after bacterial hydrolysis highlights the  
304 possible benefit of using milk products fermented with *Lb. helveticus* BGRA43 or *Lb. zaeae*  
305 LMG17315 in nutrition of these patients.

306           Taking into account the differences in the levels of specific antibodies in sera of all  
307 patients before and after the hydrolysis, the drops of specific IgE levels are perhaps the most  
308 important, since the largest frequency of patients included in our study had elevated level of IgE  
309 specific for TCMP. Following the hydrolyses, the frequency of patients with elevated level of  
310 IgE specific for TCMP hydrolysates was drastically lower. Moreover, 18 patients who had titre

311 of IgE specific for undigested TCMP several hundred times above the cut-off value showed  
312 normal levels of IgE specific to products of BGRA43 hydrolysis, while 13 of those 18 patients  
313 showed normal levels of IgE specific for TCMP-Z hydrolysate. Comparing the differences in  
314 serum levels of IgE against two different hydrolysates, it could be concluded that hydrolysis with  
315 LMG17315 demonstrated better effect, although BGRA43 had similar impact for the majority of  
316 the patients. This is interesting since the efficacy of BGRA43 hydrolysis was higher, given that  
317 about 30%  $\alpha$ -lactalbumin and 40% of  $\beta$ -lactoglobulin remained intact in TCMP-Z hydrolysate.  
318 This could mean that  $\alpha$ -lactalbumin and  $\beta$ -lactoglobulin, which have been for long time  
319 considered the most important milk allergens (Fiocchi et al., 2010), are not source of majority of  
320 immunoreactive epitopes for patients tested in this study, and that caseins are critically involved  
321 in their immunoreactivity to TCMP.

322 Although the hydrolysates obtained were not characterised in detail, the results proved  
323 the concept of the ability proteinases to destroy immunogenic epitopes in TCMP, which was  
324 unambiguously corroborated with the results of competitive ELISA. It should be mentioned,  
325 however, that LAB proteinases (or CEPs), responsible for the observed digestion, are not capable  
326 of producing di- and tri-peptides, nor free amino acids. In addition, it is known that CEP  
327 hydrolysis of only  $\beta$ -casein may lead to generation of more than a hundred different  
328 oligopeptides (Juillard et al., 1995). Further determination of diversity and immunogenicity of  
329 these epitopes as well as the cleavage sites targeted by analysed lactobacilli proteinases could  
330 deepen our understanding of mechanism of the reactions addressed and will be the subject of  
331 further studies.

332 Hydrolysis of immunogenic milk epitopes, demonstrated in our study, presents an  
333 important feature of lactobacilli, significant for both application and fundamental research. Our

334 results show that BGRA43 and LMG17315 could be applied in the production of fermented milk  
335 products or extensively hydrolysed milk formulas, which would be largely free from epitopes  
336 shown here to be recognised by the immune response and to thus present potential health  
337 problems, at least for the patient groups analysed in our study.

338         However, as our study demonstrated, the efficacy of bacteria to destroy immunogenic  
339 determinants present in TCMP, the antigenicity of TCMP-RA and TCMP-Z hydrolysates has to  
340 be analysed *in vivo*, as these newly formed products might possess new, previously unexpressed,  
341 epitopes that could potentially induce immunogenic reaction after consumption.

342         Comparative studies of the various hydrolysed formulas present on the market indicated  
343 that not all formulas have the same protective benefit in prevention and treatment of atopic  
344 diseases in infants and children (Greer, Sicherer, & Burks, 2008). Thus, formulation of novel  
345 non-immunogenic foods is expected to increase in the next decades, which is particularly  
346 important for infants and children for whom ingestion of milk and milk products is necessary,  
347 but who are at the same time most affected with food-associated immune reaction (Sicherer &  
348 Sampson, 2014).

349         Nevertheless, the presence of antibodies to analysed bacterial antigens in rare patients'  
350 sera suggests the need for screening for the antibodies specific for bacterial antigen to evaluate  
351 the efficacy and safeness of potential use of hydrolysed TCMP. Further screening of other  
352 lactobacilli strains may also provide hydrolysates without these unwanted properties and this will  
353 also be the subject of further investigations. In addition, proteolytic enzyme preparations from  
354 the lactobacilli analysed may be applied as well, bearing in mind that they are more cost-  
355 effective and easier to obtain than commercially used ones.

356 Although our research was focussed on patients suffering from different immune-related  
357 diseases, it is reasonable to suspect that individuals and children with diagnosed allergies on  
358 cows' milk or atopic diseases would also have positive outcome using TCMP hydrolysates  
359 obtained with given bacterial enzymes. Since it is known that lactobacilli may prevent and be  
360 used in treatment of various allergic diseases (Kim et al., 2014; Pohjavuori et al., 2004;  
361 Rosenfeldt et al., 2003), it is reasonable to speculate that fermented milk products can be  
362 formulated to contain both live, therapeutic bacteria and bioactive non-immunogenic peptides,  
363 generated through the activity of their proteinases.

364

## 365 **5. Conclusions**

366

367 Taking all the results together, we can conclude that with the hydrolysis of TCMP by  
368 BGRA43 and LMG17315, drastic differences in the levels of specific IgE and IgG can be  
369 observed in sera of most patients from all three investigated groups. Our findings demonstrate  
370 that both applied lactobacilli hydrolyse total cows' milk proteins through degradation of the  
371 majority of their immunogenic epitopes, even though they possess different enzymes responsible  
372 for the digestion.

373

**Table 1**

Frequencies of healthy control subjects and patients with elevated humoral immunity to RA and Z antigen solutions.

Solution	Healthy controls	Patient groups		
		ROU	GD	HM
IgG RA	2/33	2/20	0/20	1/20
IgG Z	1/33	6/20	3/20	4/20
IgE RA	4/33	0/20	0/20	1/20
IgE Z	2/33	6/20	6/20	0/20

## Figure legends

**Fig. 1.** Hydrolysis pattern of total cows' milk proteins (TCMP) by different lactobacilli strains after 3h of incubation at 37 °C. Lane S, starting substrate (TCMP); lane 1, *Lb. rhamnosus* BGT10; lane 2, *Lb. plantarum* BGHO10; lane 3, *Lb. zaeae* LMG17315; lane 4, *Lb. plantarum* BGBUK 2-5; lane 5, *Lb. plantarum* LMG18024; lane 6, *Lb. casei* ATCC393; lane 7, *Lb. plantarum* BGPV2-45a; lane 8, *Lb. plantarum* LMG9208; lane 9, *Lb. plantarum* BGGA-8; lane 10, *Lb. helveticus* BGRA43. Abbreviations are:  $\alpha$ -CN,  $\alpha$ -casein;  $\beta$ -CN,  $\beta$ -casein;  $\kappa$ -CN,  $\kappa$ -casein;  $\beta$ -Lg,  $\beta$ -lactoglobulin;  $\alpha$ -La,  $\alpha$ -lactalbumin. For reference on protein bands see Miloradovic, Kljajevic, Jovanovic, Vucic, & Macej (2015).

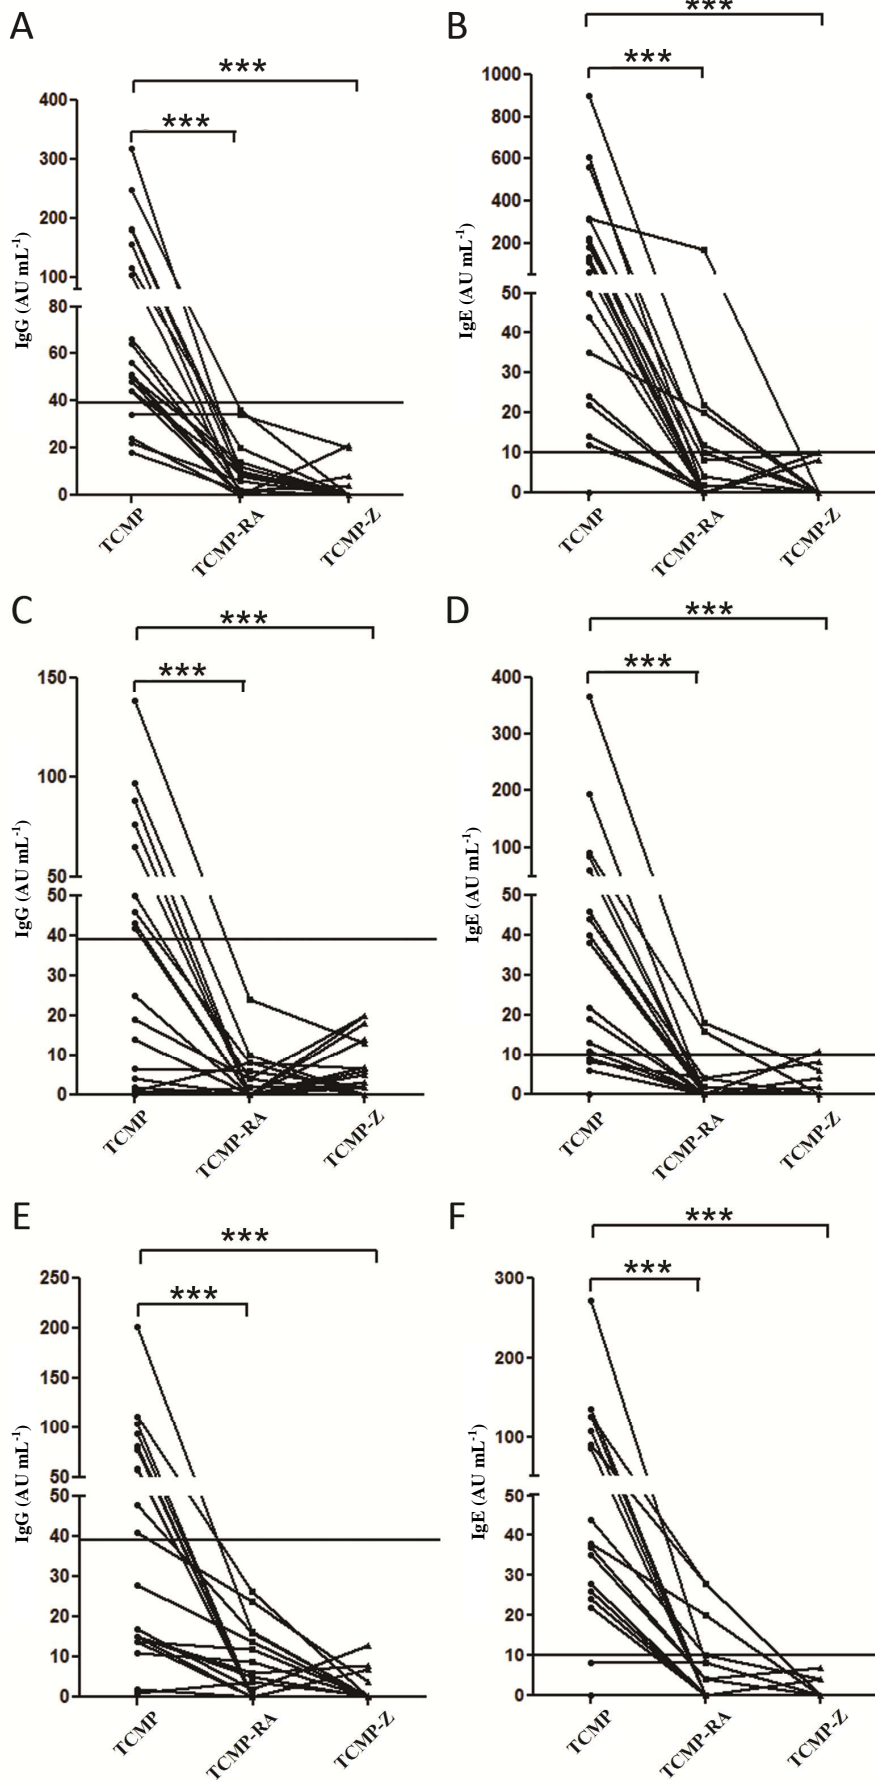

**Fig. 2.** The levels of IgG (A, C and E) and IgE (B, D and F) antibodies against unhydrolysed total cows' milk proteins (TCMP) and after the hydrolysis of TCMP with *Lb. helveticus* BGRA43 (TCMP-RA) and *Lb. zaeae* LMG17315 (TCMP-Z). The levels of antibodies specific for TCMP, TCMP-RA and TCMP-Z in sera of all patients with recurrent oral ulcerations (A, B), gastrointestinal disorders (C, D) and haematological malignancies (E, F) were determined by ELISA. Values obtained for each patient were plotted as points on the graph and connected by the line. All measurements were done in duplicate. Friedman test with Dunn's Multiple Comparison Test was used for statistical analysis, \*\*\*  $p < 0.005$  compared with control

**Fig. 3.** Competitive ELISA for determination of specificity of (A) IgG and (B) IgE from patients' sera to immunogenic epitopes of unhydrolysed total cows' milk proteins (TCMP). The mixture of sera from five patients with recurrent oral ulcerations was pre-incubated either with unhydrolysed total cows' milk proteins (×) or products from hydrolysis of TCMP

with *Lb. helveticus* BGRA43 (○) or *Lb. zae* LMG17315 (□) in final concentrations of 0, 1, 10, 100, 500 and 1000  $\mu\text{g mL}^{-1}$  and thereafter incubated in the wells pre-coated with unhydrolysed TCMP (10  $\mu\text{g mL}^{-1}$ ). All measurements were done in duplicate, calculating the mean OD450 values.
